**Interpolation:** Interpolation is a type of estimation, a method of constructing (finding) new data points based on the range of a discrete set of known data points.

For example, for an unknown function f(x), few data points are given as under.

Х	y=f(x)
Argument	Entry
0	0
1	0.8415
2	0.9093
3	0.1411
4	-0.7568
5	-0.9589
6	-0.2794

Find/estimate/interpolate the value of y=f(x) for x=2.5.

If I plot a graph for the above mentioned data point, it would look something like:

**Linear interpolation**: One of the simplest methods is linear interpolation (sometimes known as lerp). Consider the above example of estimating f(2.5). Since 2.5 is midway between 2 and 3, it is reasonable to take f(2.5) midway between f(2) = 0.9093 and f(3) = 0.1411, which yields **0.5252**.

Generally, linear interpolation takes two data points, say  $(x_a, y_a)$  and  $(x_b, y_b)$ , and the interpolant is given by:

$$y = y_a + (y_b - y_a) [(x-x_a) / (x_b-x_a)]$$

Let us try to evaluate the value of y for x=2.5 with  $(x_a,y_a)=(2,0.9093)$  and  $(x_b,y_b)=(3,0.1411)$ . y = 0.9093 + (0.1411 - 0.9093)[(2.5-2) / (3-2)] =**0.5252** 

Its quick and easy but not precise.

Find/estimate/interpolate the value of y=f(x) for x=4.

Can we apply Newton Forward Interpolation Method? Yes. Why? Because  $x_1-x_0 = x_2-x_1 = x_3-x_2 = x_n-x_{n-1}=h=2$ 

Now, 
$$u = \frac{x - x_0}{h} = \frac{4 - 3}{2} = 0.5$$

X <sub>4</sub>	70-80	<b>Y</b> <sub>4</sub>	31		

Find/estimate/interpolate the number of students who obtain marks between 40 to 45 from the above table.

h = length of the interval = 10

x = we would first find the values below 45 (i.e. <math>x=45) (and then subtract 31 [below 40] from it to get the answer for range 40 to 45)

 $x_0 = 40$  (below 40)

Now,  $u = \frac{x - x_0}{x} = \frac{45 - 40}{10} = 0.5$
